SINGLE DOSE AZITHROMYCIN

This application is a continuation-in-part of US Patent Application 60/313,867, filed August 21, 2001, which is hereby incorporated by reference herein in its entirety.

5

Field of the Invention

The present invention relates to a method of treating respiratory infection by administering a single dosage of azithromycin.

Background of the Invention

Azithromycin is the U.S.A.N. (generic name) for 9a-aza-9a-methyl-9-deoxo-9a-homoerythromycin A, a broad spectrum antimicrobial compound derived from erythromycin A. Azithromycin was independently discovered by Bright, US Pat. No. 4,474,768 and Kobrehel et al., US Pat. No. 4,517,359. These patents disclose that azithromycin and certain derivatives thereof possess antibacterial properties and are accordingly useful as antibiotics. Azithromycin may be made, formulated and administered according to procedures described in the following US patents, which are all incorporated herein in their entirety by reference: US Pat. Nos. 6,268,489; 4,963,531; 5,633,006; 5,686,587; 5,605,889; 6,068,859; 4,328,334; and 5,498,699.

Azithromycin is administered for the treatment of infections, particularly respiratory infections, and more particularly respiratory infections of the bronchial tract, lungs, and sinus. Frequently, azithromycin is prescribed for acute otitis media. Acute otitis media is an inflammation of the area behind the eardrum (tympanic membrane) in the chamber called the middle ear. Acute otitis media is an infection that produces pus, fluid, and inflammation within the middle ear.

Acute otitis media may be caused by a variety of pathogens, such as *M. catarrhalis*, *S. pneumoniae*, and *H. influenzae*. Acute otitis media is particularly common in infants and children. Azithromycin has been prescribed for the treatment of acute otitis media with a 30 mg/kg body weight total treatment dose given as a five day regimen in the US and as a three day regimen in Europe. The multiple dosages prescribed to completely cure the infection have caused compliance problems, particularly in pediatric patients. Even in the adult population, compliance with multiple dosaging regimens is not complete because of forgetfulness and other reasons. A method of treating and curing infection, particularly a microbial infection such as acute otitis media, by administering a single dose of azithromycin would significantly shorten courses of therapy and be of a great advantage to patient compliance.

A continual problem with antibiotic therapy is the emergence of resistant microbial strains. A method of treating microbial infections with a reduced risk of developing treatment-resistant strains is desirable. It is believed that a single dose azithromycin treatment provides such as reduced risk. The inflammatory cells provide a mode of transport of azithromycin to the infection site and provide a reservoir for azithromycin at the infection site. As a result, azithromycin is characterized by high and sustained concentrations in a wide range of tissues, and a particularly increased concentration at sites of infection. It is believed that a single dose therapy with azithromycin, by providing a higher initial concentration at the infection site, may help prevent less susceptible sub-populations of the pathogens initially present from becoming established. Also, a single-dose regimen will result in greater patient compliance, which should contribute to reduced emergence of less susceptible strains.

Single dose administration of azithromycin for the treatment of non-gonococcal urethritis and cervicitis due to *C. trachomatis* has been prescribed and is a therapy approved by the US Food and Drug Administration. Single dose treatment of respiratory infections in humans with azithromycin has been tested. For example, Stan Block et al. reported on single dose azithromycin (30 mg/kg) in acute otitis media in infants and children six months to twelve years of age. S. Block *et al.*, "Single-Dose Azithromycin (30 mg/kg) in Acute Otitis Media", Arguedas reported on single-dose therapy in otitis media using azithromycin in infants and children. Arguedas, A., "Single-dose therapy in otitis media", Poster Presentation at 9th European Congress of Clinical Microbiology and Infectious Diseases, Berlin, Germany, March 21-24, 1999, *Clin. Microbiol. Infect.* 1999;5 (Suppl. 3 March):28 (Abstr). A single oral dose of 2g azithromycin was administered to healthy male subjects in tests of gastrointestinal side effects reported in US Pat. No. 6,068,859. Despite these reports, there exists a need for a method of treating respiratory infections such as acute otitis media with a single dose of azithromycin such that the infection is cured.

Summary of the Invention

The present invention fulfills these needs by providing a method of treating a respiratory infection in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is about 35mg/kg body weight or greater. In another embodiment, the invention is directed to a method of treating a respiratory infection in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is within the range of about 0.7 to 3.5 g. A further embodiment is directed to a method of treating a respiratory infection caused by *S. pneumoniae* isolates containing a

mef A gene in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is about 35mg/kg body weight or greater.

Brief Description of the Drawings

5

Figures 1a and 1b show the eradication of *H. influenzae* in a gerbil model of middle ear infection.

Detailed Discussion

10 The invention provides a method of treating respiratory infections in a human in need thereof by administering a single dose of azithromycin. The human patient may be an adult sixteen years of age or older, a child under sixteen years of age, or a young child twelve years of age or younger. By "single dose" is meant a dosage that is administered only once over a 28-day period. The dosage may be administered in a single dosage form, such as one
15 capsule or tablet, or may be divided, e.g. constituted by more than one dosage form, such as by multiple capsules or tablets that are taken at or about the same time. Any type of dosage form may be used, such as capsule, tablet, liquid suspension for oral administration, or liquid for intravenous administration.

The "single dose" of the invention is formulated for immediate release and is not
20 formulated for controlled, sustained or delayed release. For example, an orally administered azithromycin single dose administered according to the present invention is preferably in a form such that it releases azithromycin to the human gastrointestinal tract at a rate such that the total amount of azithromycin released therein is more than 4 mg of azithromycin per kg of patient weight in the first fifteen minutes after ingestion and more preferably is more than 40
25 mg of azithromycin per kg of weight in the first six hours after ingestion.

Azithromycin can be employed in its pharmaceutically acceptable salts and also in anhydrous as well as hydrated forms, such as the di- and mono-hydrates. All such forms are within the scope of this invention. The azithromycin employed is preferably the dihydrate, which is disclosed in published European Patent Application 0 298 650 A2.

30 Under the inventive methods, respiratory infections in humans are treated by administering azithromycin in a single dose of about 35mg/kg body weight or greater. Preferably, the single dose is between about 35mg/kg and 60mg/kg body weight, and yet more preferably between about 40mg/kg and 50mg/kg body weight. In other embodiments, the single dose is between about 35mg/kg and 40mg/kg, between about 40mg/kg and
35 45mg/kg, between about 45mg/kg and 50mg/kg, or between about 50mg/kg and 60mg/kg. In another embodiment, the single dose of azithromycin is administered at a dose within the

range of about 0.7 to 3.5 g, preferably a dose within the range of about 0.7 to 1.5 g or about 1.5 to 3.1g. Yet more preferably the dose is within the range of about 1.5 to 1.9 g, and more preferably within the range of about 2.1 to 3.1 g. In other embodiments, the single dose is selected from the group consisting of 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, 2.9, 3.0 and 3.1g.

The methods of the invention may be used to treat infections caused or mediated by different pathogens. Preferably, the pathogen is selected from *S. aureaus*, *S. pneumoniae*, *H. influenzae*, *M. catarrhalis* and *S. pyrogenes*, and more preferably is selected from *S. pneumoniae*, *H. influenzae* and *M. catarrhalis*. The invention preferably is directed to treating a respiratory infection such as acute otitis media caused or mediated by one of these specified pathogens.

Examples

1.0 Single Dose Azithromycin Pediatric Test

A trial was performed using a single 30-mg/kg dose of azithromycin in the treatment of otitis media in pediatric patients undergoing diagnostic tympanocentesis. Children six months to twelve years were enrolled. Of the patients who had a pathogen identified at baseline by culture, 81% were cured by the single dose therapy. Cure was defined by a clinical assessment at day 24-28 showing complete resolution of all signs and symptoms of acute otitis media. Cure rates were highest for *M. catarrhalis* (10/10; 100%) followed by *S. pneumoniae* (67/76; 88%) and *H. influenzae* (28/44; 64%).

Twelve children were found to have an infection with an isolate of *S. pneumoniae* resistant to macrolides. Five children had an infection of an isolate that contained the erm B gene. Only two of these five patients were cured at day 28. Seven children had an infection of an isolate that contained the mef A gene. Six of these seven patients were cured at day 28. The patient who failed was resolving the disease in the ear from which the baseline isolate was obtained but had a different *S. pneumoniae* isolate recovered on day 4 from the opposite ear. The high efficacy in the patients whose *S. pneumoniae* isolate were found to contain the mef A gene was unexpected and surprising.

2.0 Single Dose Azithromycin Animal Tests

Laboratory experiments with azithromycin suggest that it is the total amount of drug rather than the interval of the drug dosing regimen that determines the concentration at the infection site and results in efficacy. Acute murine models challenged with *S. pneumoniae*, *H. influenzae*, *E. faecalis* or *S. pyrogenes* showed that azithromycin was superior in efficacy when given as a single oral dose as determined by PD₅₀ measurements (see Table 1).

Table 1. The Effect of Dose Regimen on Efficacy of Azithromycin in Murine

Models. Pathogen	MIC (μ g/ml)	Dosing Regimen	Oral PD50 (mg/kg/day)
5 <i>H. influenzae</i>		3 days	181.6 (180.1-183.1)
		2 days	49.9 (41.5-58.5)
		1 day	25.3 (14.3-36.2)
10 <i>S. pyogenes</i>	0.06	3 days	3.8 (3.8-3.9)
		2 days	2.5 (1.8-3.3)
		1 day	1.0 (0.6-1.4)
15 <i>E. faecalis</i>		3 days	59.3 (27.5-91.2)
		2 days	42.7 (42.2-43.2)
		1 day	14.8 (10.2-19.5)
20 <i>S. pneumoniae</i>	0.06	3 days	49.4 (28.1-70.8)
		2 days	27.6 (22.8-32.4)
		1 day	20.4 (16.4-24.3)

The improvement in the PD₅₀ for treatment of *H. influenzae* was especially noteworthy. In a gerbil model of middle ear infection, two different strains of *H. influenzae* 54A1100 and 54A1218 were shown to be as efficaciously treated with azithromycin administered as a single dose as the same total dose given over two or three days (see Table 2). In these experiments, colony-forming units (CFU) are assessed from the bulla wash of five gerbils per time point. The ED₅₀ values reflect the dose in which the CFU recoverable from the bulla wash is 50% of the non-treated animals.

Table 2. The Effect of Dose Regimen on Efficacy of Azithromycin in the Gerbil

Middle Ear Infection Model. Pathogen	MIC (μ g/ml)	Dosing Regimen	ED50 (mg/kg/total)
35 <i>H. influenzae</i>	1	3 days	162.9 (140-185.9)
		2 days	138.1 (118.7-157.6)
		1 day	138.1 (118.7-157.6)

The in vivo kill kinetics demonstrated that the one-day dosing therapeutic regimen resulted in the most rapid eradication of the pathogens (Figure 1) and, in the case of 54A1100, was the only dosing regimen that leads to complete clearance. Thus, a single dose therapy has advantages over a more prolonged course of therapy.

CLAIMS

1. A method of treating a respiratory infection in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is about
5 35mg/kg body weight or greater.
2. The method of claim 1 wherein the dose is between about 35mg/kg and 60mg/kg body weight.
3. The method of claim 2 wherein the dose is between about 40mg/kg and 50mg/kg body weight.
- 10 4. The method of claim 2 wherein the human is an adult sixteen years of age or older.
5. The method of claim 2 wherein the respiratory infection is acute otitis media.
6. A method of treating a respiratory infection in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is within the range of about 0.7 to 3.5 g.
- 15 7. The method of claim 6 wherein the respiratory infection is acute otitis media.
8. The method of claim 6 wherein the dose is within the range of about 0.7 to 1.5 g.
9. The method of claim 6 wherein the dose is within the range of about 1.5 to 3.1 g.
10. The method of claim 9 wherein the dose is within the range of about 1.5 to 1.9 g.
11. The method of claim 9 wherein the dose is within the range of about 2.1 to 3.1 g.
- 20 12. The method of claim 9 wherein the human is an adult sixteen years of age or older.
13. A method of treating a respiratory infection caused by *S. pneumoniae* isolates containing a *mef A* gene in a human comprising administering to a human in need thereof a single dose of azithromycin wherein the dose is about 35 mg/kg body weight or greater.
- 25 14. The method of claim 13 wherein the dose is between about 35mg/kg and 60mg/kg body weight.
15. The method of claim 13 wherein the dose is between about 40mg/kg and 50mg/kg body weight.
